Part III — Extremal Graph Theory

Definitions

Based on lectures by A. G. Thomason
Notes taken by Dexter Chua
Michaelmas 2017

These notes are not endorsed by the lecturers, and I have modified them (often significantly) after lectures. They are nowhere near accurate representations of what was actually lectured, and in particular, all errors are almost surely mine.

Turán’s theorem, giving the maximum size of a graph that contains no complete \( r \)-vertex subgraph, is an example of an extremal graph theorem. Extremal graph theory is an umbrella title for the study of how graph and hypergraph properties depend on the values of parameters. This course builds on the material introduced in the Part II Graph Theory course, which includes Turán’s theorem and also the Erdős–Stone theorem.

The first few lectures will cover the Erdős–Stone theorem and stability. Then we shall treat Szemerédi’s Regularity Lemma, with some applications, such as to hereditary properties. Subsequent material, depending on available time, might include: hypergraph extensions, the flag algebra method of Razborov, graph containers and applications.

Pre-requisites

A knowledge of the basic concepts, techniques and results of graph theory, as afforded by the Part II Graph Theory course, will be assumed. This includes Turán’s theorem, Ramsey’s theorem, Hall’s theorem and so on, together with applications of elementary probability.
Contents

3  Supersaturation  5
4  Szemerédi’s regularity lemma  6
5  Subcontraction, subdivision and linking  7
6  Extremal hypergraphs  8
1 The Erdős–Stone theorem

**Definition** (Turán graph). The Turán graph $T_r(n)$ is the complete $r$-partite graph on $n$ vertices with class sizes $\lfloor n/r \rfloor$ or $\lceil n/r \rceil$. We write $t_r(n)$ for the number of edges in $T_r(n)$.

**Notation.** We denote by $K_r(t)$ the complete $r$-partite graph with $t$ vertices in each class.
2 Stability
3 Supersaturation
4 Szemerédi’s regularity lemma

Definition (Density). Let $U, W$ be disjoint subsets of the vertex set of some graph. The number of edges between $U$ and $W$ is denoted by $e(U, W)$, and the density is

$$d(U, W) = \frac{e(U, W)}{|U||W|}.$$

Definition ($\varepsilon$-uniform pair). Let $0 < \varepsilon < 1$. We say a pair $(U, W)$ is $\varepsilon$-uniform if

$$|d(U', W') - d(U, W)| < \varepsilon$$

whenever $U' \subseteq U$, $W' \subseteq W$, and $|U'| \geq \varepsilon |U|$, $|W'| \geq \varepsilon |W|$.

Definition (Equipartition). An equipartition of $V(G)$ into $k$ parts is a partition into sets $V_1, \ldots, V_k$, where $\left\lfloor \frac{n}{k} \right\rfloor \leq V_i \leq \left\lceil \frac{n}{k} \right\rceil$, where $n = |G|$.

We say that the partition is $\varepsilon$-uniform if $(V_i, V_j)$ is $\varepsilon$-uniform for all but $\varepsilon (k^2)$ pairs.
5 Subcontraction, subdivision and linking

Definition. Let $G$ be a graph, $e = xy$ an edge. Then the graph $G/e$ is the graph formed from $G \setminus \{x, y\}$ by adding a new vertex joined to all neighbours of $x$ and $y$. We say this is the graph formed by contracting the edge $e$.

Definition ((Sub)contraction). A contraction of $G$ is a graph obtained by a sequence of edge contractions. A subcontraction of $G$ is a contraction of a subgraph. We write $G \succ H$ if $H$ is a subcontraction of $G$.

Definition (Subdivision). If $H$ is a graph, $TH$ stands for any graph obtained from $H$ by replacing its edges by vertex disjoint paths (i.e. we subdivide edges).

Definition ($k$-linked graph). We say $G$ is $k$-linked if there exists vertex disjoint $s_i$-$t_i$ paths for $1 \leq i \leq k$ for any choice of these $2k$ vertices.

Definition ($S$-cut). Given $S \subseteq V(G)$, an $S$-cut is a pair $(A, B)$ of subsets of the vertices such that $A \cup B = V(G)$, $S \subseteq A$ and $e(A \setminus B, B \setminus A) = 0$. The order of the cut is $|A \cap B|$.

We say $(A, B)$ avoids $C$ if $A \cap V(C) = \emptyset$.
